M1 + stale 20 + dt 25 (solid)

42 multi-animal SLAP-2M sessions: 674,111 video frames $\times$ 6 cameras = 4,044,666 camera-frames, holding 7,374,061 labelled detections. The 32 one-animal sessions are

EXCLUDED: 0 switches and 0 misgrouped detections under both configurations, so pooling them changed only the denominator

misgrouped = a LABELLED DETECTION — one animal, one camera, one frame — over a GT box ($\text{IoU} \geq 0.5$)

whose id disagrees with that box under the OPTIMAL tracker-id $\rightarrow$ GT-index permutation for that

camera, solved with linear_sum_assignment exactly as IDF1 does internally
